Spring Semester 2018

KAIST EE209

Programming Structures for Electrical Engineering

Mid-term Exam

Name:		
Student ID:		
and focus your a help only in un concise and pre-	derstanding the quise in your answninutes (1:00 PM	, but closed electronic device. Read the questions carefully as been asked. You are allowed to ask the instructor/TAs for uestions, in case you find them not completely clear. Beers and state clearly any assumption you may have made. — 3:45 PM) to complete your exam. Be wise in managing
Question 1	/ 10	
Question 2	/ 20	
Question 3	/ 15	
Question 4	/ 20	
Question 5	/ 20	
Question 6	/ 15	

Total

_____/ 100

Name:

Student ID:

1. (10 points) Numbers

(a) (6 points) What is the range of decimal numbers that can be represented using 7 bits for each format?

2's complement:_____ to _____

1's complement:______ to _____

Unsigned binary:______ to _____

(a) (2 points) Convert the 8-bit signed 2's complement hex number 0xAB to decimal:

(b) (2 points) Compute the decimal value of -12 ^ 23 using 8-bit 2's complement encoding:

- 2. (20 points) Small programs
 - (a) (10 points) Identify all the bugs in the following program.

```
#include <stdio.h>

struct student {
   char name[3];
   int counter;
};

void increment(const struct student* s)
{
   s.counter++;
}

int main()
{
   struct student s;
   strcpy(s.name, "kim");
   s.counter = 0;
   increment(s);
   return 0;
}
```

Name:

Student ID:

(b) (10 points) What is the output of the following program?

```
#include <stdio.h>
#include <string.h>
int main()
 char s[] = "lbjtu\0abc", *p;
 for (p = s; *p; p++)
   --*p;
 printf("s: %s\n", s);
 printf("s + 6: %s\n", s + 6);
 printf("strlen(s): %zu\n", strlen(s));
 printf("strlen(s + 6): %zu\n", strlen(s + 6));
 printf("sizeof(s): %zu\n", sizeof(s));
 return 0;
}
Output:
s + 6: _____
strlen(s):
strlen(s + 6):_____
sizeof(s):_____
```

3. (15 points) Functions

Write a function that finds the n^{th} fibonacci number. The Fibonacci series are the integers in the following sequence:

```
0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, \dots
```

where the first two integers in the sequence are 0 and 1, and each subsequent integer is the sum of the previous two integers. For example, the 0th fibonacci number is 0, and the 4th fibonacci number is 3.

(a) (5 points) Implement the Fibonacci function using recursion. Assume input n is a non-negative integer.

```
int fibonacci_recursive(int n)
{
```

}

(b) (10 points) Implement the Fibonacci function without using recursion. Assume input n is a non-negative integer.

```
int fibonacci_iterative(int n)
{
```

}

4. (20 points) Dynamic storage

Suppose we are dynamically allocating many blocks of memory. While we can free each allocated block individually, it may be more convenient to free all of them together through a single function. To implement this functionality, we will maintain a dynamically-allocated array p of pointers to all the allocations using these two functions:

- *mymalloc*: allocates a memory block and add its pointer to p
- *myfree*: frees all the allocated memory blocks using p

You may use the following functions and assume that memory is always available.

```
void *malloc(size_t size);
void *realloc(void *ptr, size_t size);
void free(void *ptr);

Fill in the lines below:

#include <stdio.h>
#include <stdlib.h>

void* mymalloc(size_t size, void*** p, int* psize)
{

    *p = ______
    void *temp = _____
    return temp;
}
```

5. (20 points) Linked list

In addition to the linked list functions covered in class (Table_create, Table_add, Table_search, and Table_free), implement functions for updating and deleting individual nodes. Duplicates keys may exist, and the following structs are used:

```
struct Node {
   const char *key;
   int value;
   struct Node *next;
};

struct Table {
   struct Node *first;
};
```

(a) (10 points) Implement the update function, which finds all the nodes with the given key and changes their values to the given value.

```
void Table_update(struct Table *t, const char *key, int value)
{
```

}

(b) (10 points) Implement the delete function, which finds all the nodes with the given key and deletes them. Make sure the remaining nodes still form a linked list.

```
void Table_delete(struct Table *t, const char *key)
{
```

}

- 6. (15 points) C++
 - (a) (10 points) What is the output of the following program? Briefly explain why each line is printed.

```
#include <iostream>
using namespace std;
class B
{
 public:
  B() {
    cout << "B()" << endl;</pre>
  ~B() {
   cout << "~B()" << endl;</pre>
  void f() {
   cout << "B::f()" << endl;</pre>
  virtual void vf() {
    cout << "B::vf()" << endl;</pre>
  }
};
class D : public B
{
 public:
  D() {
   cout << "D()" << endl;</pre>
  }
  ~D() {
   cout << "~D()" << endl;</pre>
  void f() {
    cout << "D::f()" << endl;</pre>
  void vf() {
    cout << "D::vf()" << endl;</pre>
};
```

```
int main()
{
    B b;
    D d;
    D* e = (D*)&b;
    d.f();
    d.vf();
    e->f();
    e->vf();
}
```

Output:

(b) (5 points) What is the output of this program? (Hint: look at the arguments of the swap function carefully.)

```
#include <iostream>
 using namespace std;
 void swap(int& a, int b)
   int temp = a;
   a = b;
   b = temp;
 }
 int main()
   int a = 1;
   int b = 2;
   int c = 3;
   swap(a,b);
   cout << "swap(a,b):" << a << " " << b << " " << c << endl;</pre>
   swap(b,c);
   cout << "swap(b,c):" << a << " " << b << " " << c << endl;</pre>
   cout << "swap(c,a):" << a << " " << b << " " << c << endl;</pre>
 }
Output:
 swap(a,b): _____
 swap(b,c): _____
 swap(c,a): _____
```
